EXP.NO-13	Limitations of Low-Code Platforms for a Complex Enterprise Use Case

AIM:

To analyze the technical, architectural, and operational limitations of low-code platforms such as Zoho Creator when used for a complex, enterprise-scale Patient Appointment & Scheduling Management system.

THEORY:

Low-code platforms accelerate form, report, dashboard, and workflow creation. However, hospital-scale applications can face limitations as record volumes, integration complexity, and security requirements increase.

Customization Constraints:

Zoho Creator provides reusable components and Deluge workflows, but specialized scheduling algorithms, sophisticated clinical interfaces, and complex multi-provider rules may require custom code or external services.

Scalability and Performance Bottlenecks:

High appointment volumes, many concurrent users, automated reminders, and report queries may require careful filtering, pagination, resource monitoring, and service-level evaluation.

Vendor Lock-in and Proprietary Codebases:

Deluge scripts, Creator forms, and platform-specific workflows may not migrate directly to a conventional application stack. Data exports do not guarantee complete portability of business logic.

Complex Integration Challenges:

Integration with hospital information systems, laboratory services, payment systems, and external identity providers may require secure APIs, mapping, data governance, and bespoke error handling.

Case Study Scenario: Global Supply Chain & Predictive Logistics Engine

The Enterprise Requirement: A hypothetical healthcare organization plans to coordinate appointments across many hospitals, specialist clinics, doctors, and departments, with real-time availability, schedule conflict prevention, centralized analytics, and secure patient identity verification.

The Platform Chosen: Zoho Creator is considered because it rapidly provides forms, reports, user permissions, automation, and dashboards, as demonstrated by the Patient Appointment & Scheduling Management project.

Identified Limitations During Implementation:

1. Customization Wall:
   Advanced appointment allocation may need optimization based on emergency priority, doctor workload, department capacity, and cross-hospital transfers. Such algorithms may exceed what is convenient to maintain in a visual workflow.

2. Database Schema Rigidity:
   Large historical appointment datasets and linked subforms increase the importance of efficient retrieval, controlled paging, and well-defined record access. The project addresses some of these concerns with an Appointment Services subform and targeted Deluge queries, but enterprise-scale performance would require testing.

3. Integration and Compliance Complexity:
   Connecting multiple hospital systems demands secure authentication, data minimization, auditability, and careful management of sensitive personal information. Connector availability does not eliminate integration design work.

4. Licensing and Scaling Costs::
   Additional users, environments, integrations, and higher transaction volumes can affect operating costs. A long-term architecture decision requires a cost and capacity comparison.

RESULT:

The case study illustrates that Zoho Creator is effective for rapidly developing the current Patient Appointment & Scheduling Management application, including booking forms, role permissions, workflows, and analytics. For a hypothetical enterprise-wide hospital network, customization, scale, interoperability, data protection, vendor dependence, and licensing may introduce limitations. The assessment is analytical and does not claim that large-scale load tests were performed on the project
